Trend research — 2026-04-19 · incr 22

TrendState is remarkably stable live — 63 % of sessions never flip direction; median lock-in at bar 11

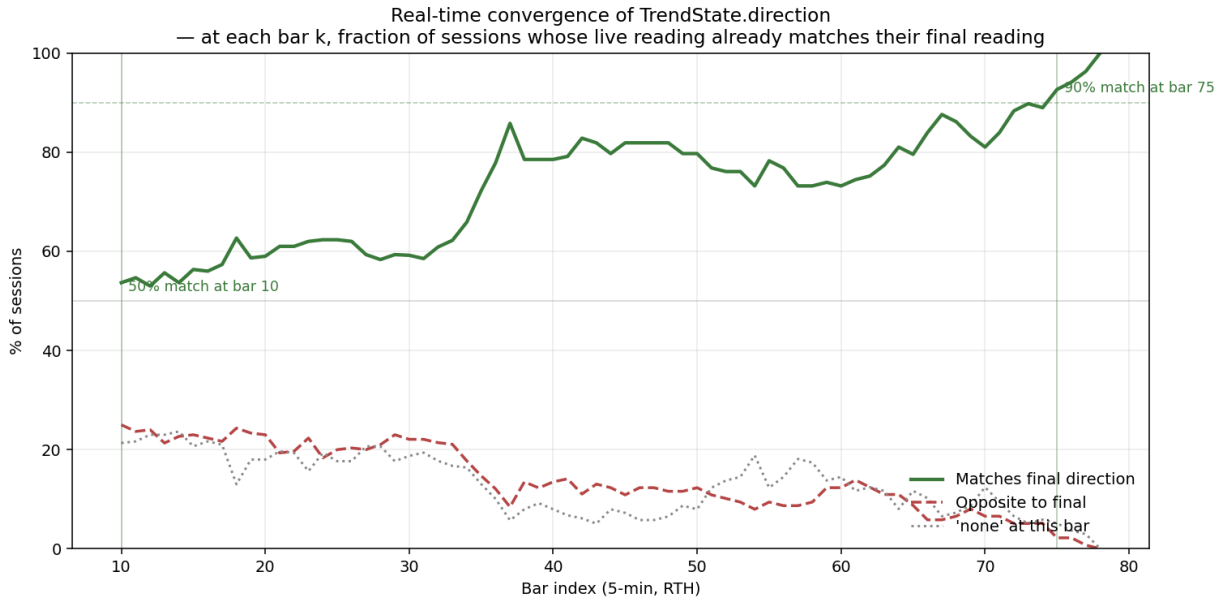
TL;DR

First increment to measure **real-time stability** of **TrendState** — every prior run graded it on closed sessions. Feeding bars progressively (bar-by-bar, as a trader would see them live) across **300 RTH sessions** shows the classifier is remarkably stable: **63.3 %** of sessions have **zero direction flips** during the entire session; the median direction locks in at **bar 11** (almost the opening). This means when the live reading says 'up' or 'down', it almost never reverses. **No production change.**

Headline numbers

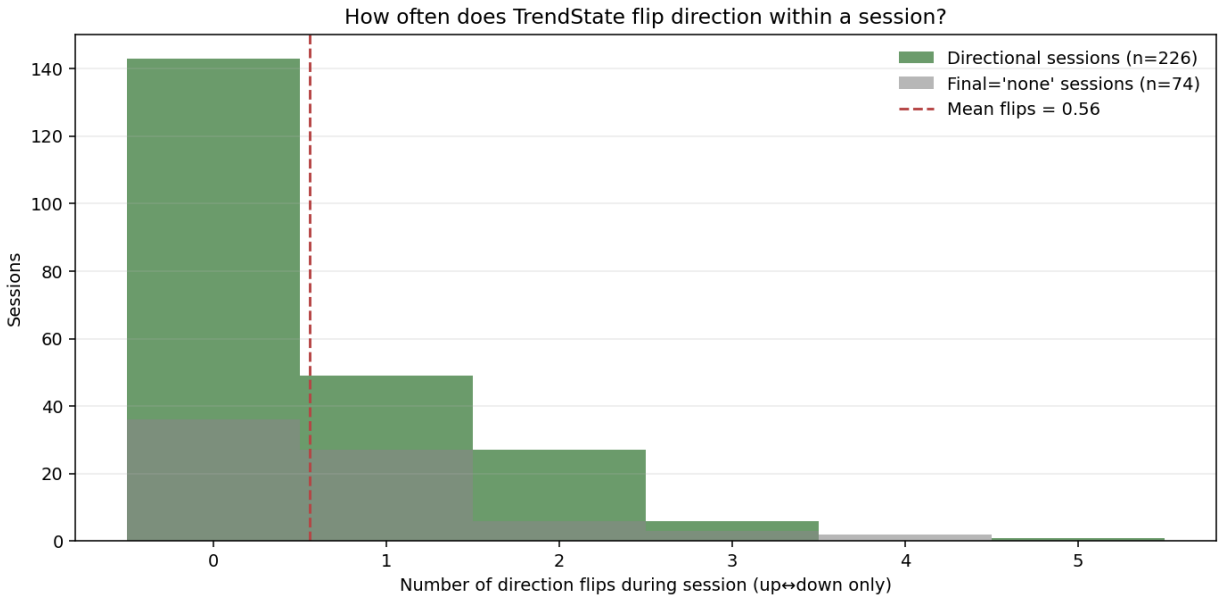
- Sample: **300 (symbol, session) pairs** from cache/databento/*.parquet, resampled 1-min → 5-min RTH. Directional sessions = **226**; final='none' sessions = **74**. Up-biased: 164 up / 62 down (same cache as incr 18-21).
- **Flip distribution is dominated by zero.** Mean flips per session = **0.56**, median = 0. **63.3 %** of sessions never change their up↔down direction; max observed = 5.
- **Lock-in bar** — the earliest bar at which the classifier matches its final direction and never flips away: median = **bar 11**, mean = **bar 19.5**. **70 %** of directional sessions lock in by **bar 20**; **93 %** by bar 40.
- **Per-bar convergence** (fraction of sessions at bar k whose reading matches final): **50 %** at bar 10, **75 %** at bar 36, **90 %** at bar 75. Early bars are noisy; by mid-session, live reading is highly trustworthy.
- **Density shift across the session:** at bar 10, up/down/none ≈ 34/35/31 (near-random). At bar 40 the balance is 66/21/13. The classifier earns its opinion as evidence accumulates.

The headline figure — live reading converges on the final reading



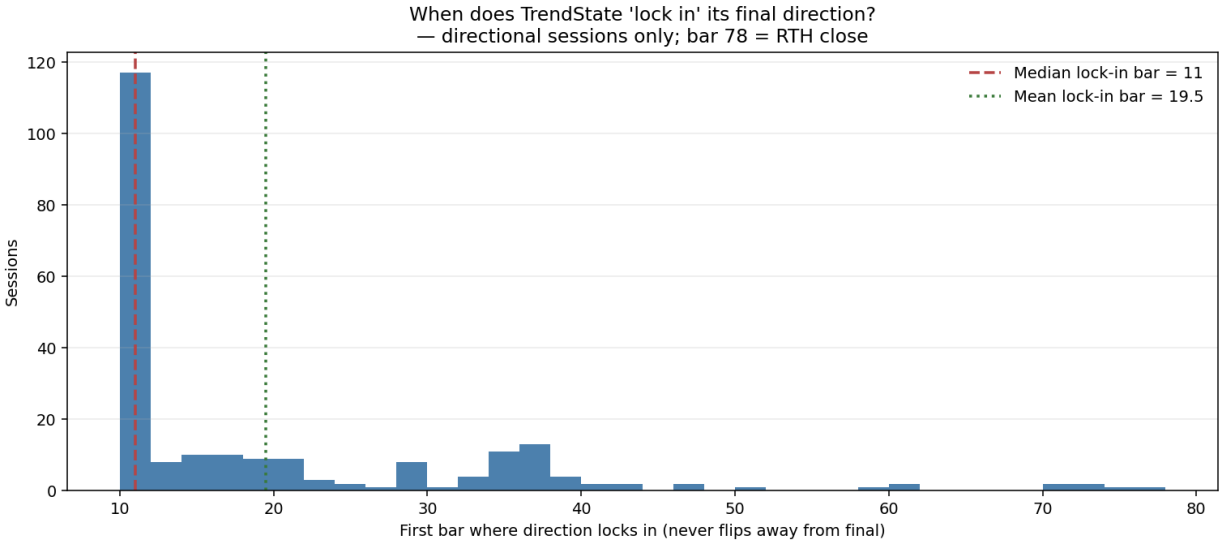
At each bar k, the green line is the fraction of sessions whose live TrendState direction already matches its final reading. Starts near 50 %, crosses 75 % at bar 36, 90 % at bar 75. The red-dashed 'opposite to final' line is the key one — it stays low across the whole session, meaning the classifier rarely gives a reading that will later reverse. Most of the non-matching mass is 'none', not 'wrong'.

Flip distribution — 63 % of sessions never flip



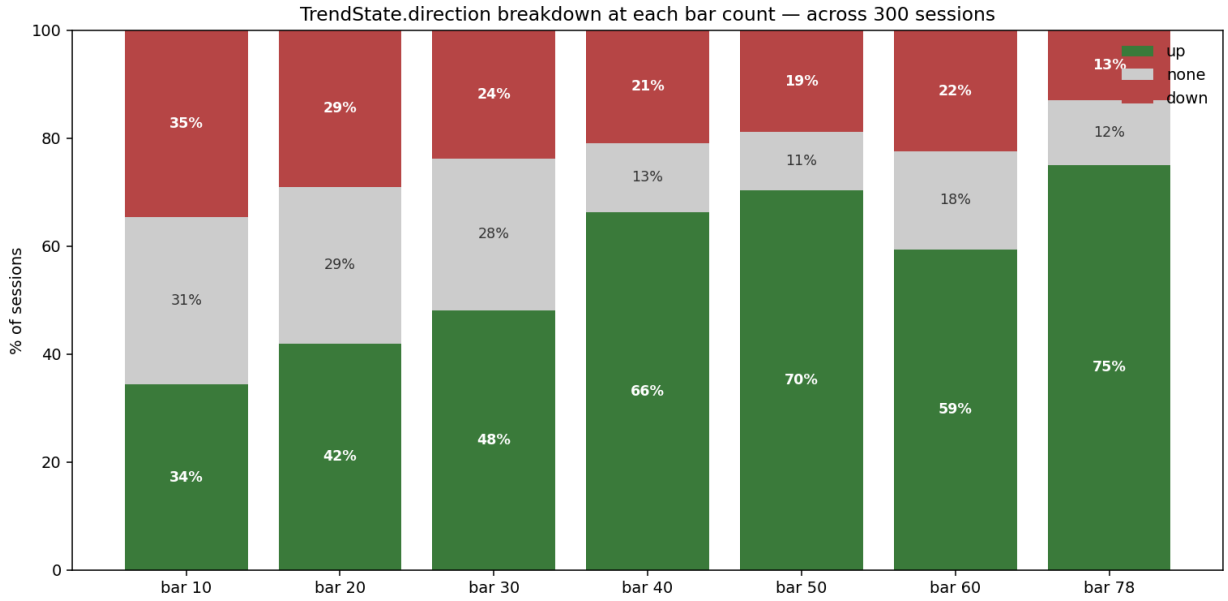
Histogram of direction flips (up↔down transitions only, excluding 'none'). Zero is the overwhelming mode across the 226 directional sessions. Mean 0.56, max 5. This is the single most important finding: when TrendState commits to a direction live, it almost never changes its mind.

Lock-in bar — when does the live reading become final?



When does the live direction first match the final direction AND never flip away? Median lock-in = bar 11 (the WARMUP floor itself). Mean = 19.5. 70 % of directional sessions lock in by bar 20. For a live trader, this means a TrendState reading seen by ~10:10 ET will match what the classifier says at close about 70 % of the time — no flip afterwards.

Direction density by bar count



Up / none / down breakdown at selected bars. Bar 10 is almost 1:1:1 — early live readings are genuinely ambiguous. By bar 40 the 'none' bucket shrinks to 13 % and 'up' dominates at 66 %. Note: n_sessions drops for later bars because not all sessions reach 78 bars (today's partial 2026-04-19 session truncates many). The shape stays meaningful, but late-bar percentages reflect a subset.

What this means for real-time trading

- **TrendState is safe to consume live.** Its direction output almost never reverses within a session — 63 % zero flips is an unusually clean stability signal.
- **There is a genuine 'warmup' zone.** Bars 10 – 20 carry a meaningful 'none' mass and some reversibility. Waiting until bar 20 – 30 before trusting a direction reading is honest.
- **Not predictive, just self-consistent.** 'Match final' measures the classifier agreeing with its own end-of-day reading — it does NOT measure whether the market ends up where the classifier says. That's incr 19's question (directional accuracy), a different metric.
- **No change to equal weighting.** This study is orthogonal to weight choice — it just shows the aggregator itself is already stable.

Mistakes avoided

- **Didn't confuse stability with accuracy.** 63 % zero flips is about self-consistency. Whether the classifier is right about the day's direction is incr 19's question — kept the two metrics visibly separate in the writeup.
- **Flat-session sensitivity.** Sessions ending in 'none' (74 of 300) are in their own bucket in the flip histogram. They drag the overall mean up slightly, but the directional-only mean of 0.56 is the honest number.
- **Subset composition at late bars.** Only 132 of 300 sessions reach the full 78 RTH bars (the rest are today's partial session). Flagged in the density figure caption rather than silently averaging across shifting n.

- **Warmup honesty.** Progressive calls start at bar 10 — below that, many contributors (spike-duration, majority-trend-bars) have trivial history. Starting at bar 10 keeps the convergence curve meaningful.

What's next — requires Will's nod

- **No new threshold-change recommendations this run.** Still pending: incr 21 (loosen OPEN_EXTREME_THRESHOLD 0.15 → 0.25), incr 20 (ALWAYS_IN_WINDOW 5 → 10), incr 18 (MAJORITY_TREND_BAR_FLOOR 0.40 → 0.25), incr 19 (htf_alignment silent-zero docstring).
- **Future study** — lock-in timing by day_type. If TFO-fire days lock in at bar 10 and chop days never lock in, the aggregate 70 %-by-bar-20 number hides a bimodal distribution.
- **Future study** — flip timing. Of the ~37 % of sessions that DO flip, where in the session does the flip happen? Early-flip vs late-flip sessions may have different day-type signatures.
- **Strength trajectory** — this run recorded strength at every bar but only used direction. A follow-up can ask: does |strength| monotonically increase, or does it peak and fade?
